Omega Test

Orientative Interpretation Results Guide

General Information

Omegas or essential fatty acids are polyunsaturated fats that play very important functions in the health and vitality of our body. Our current diet has an imbalance between omega 3 and omega 6 (specifically we ingest an excess of omega 6 that favors inflammatory processes).

The Omega Test is a study that allows us to determine the levels of different fatty acids in the blood to assess our current health status and type of diet. It includes the quantification of omega 3, omega 5, omega 6, omega 7 and omega 9 together with the determination of saturated and unsaturated fatty acids (mono / poly and cis / trans).

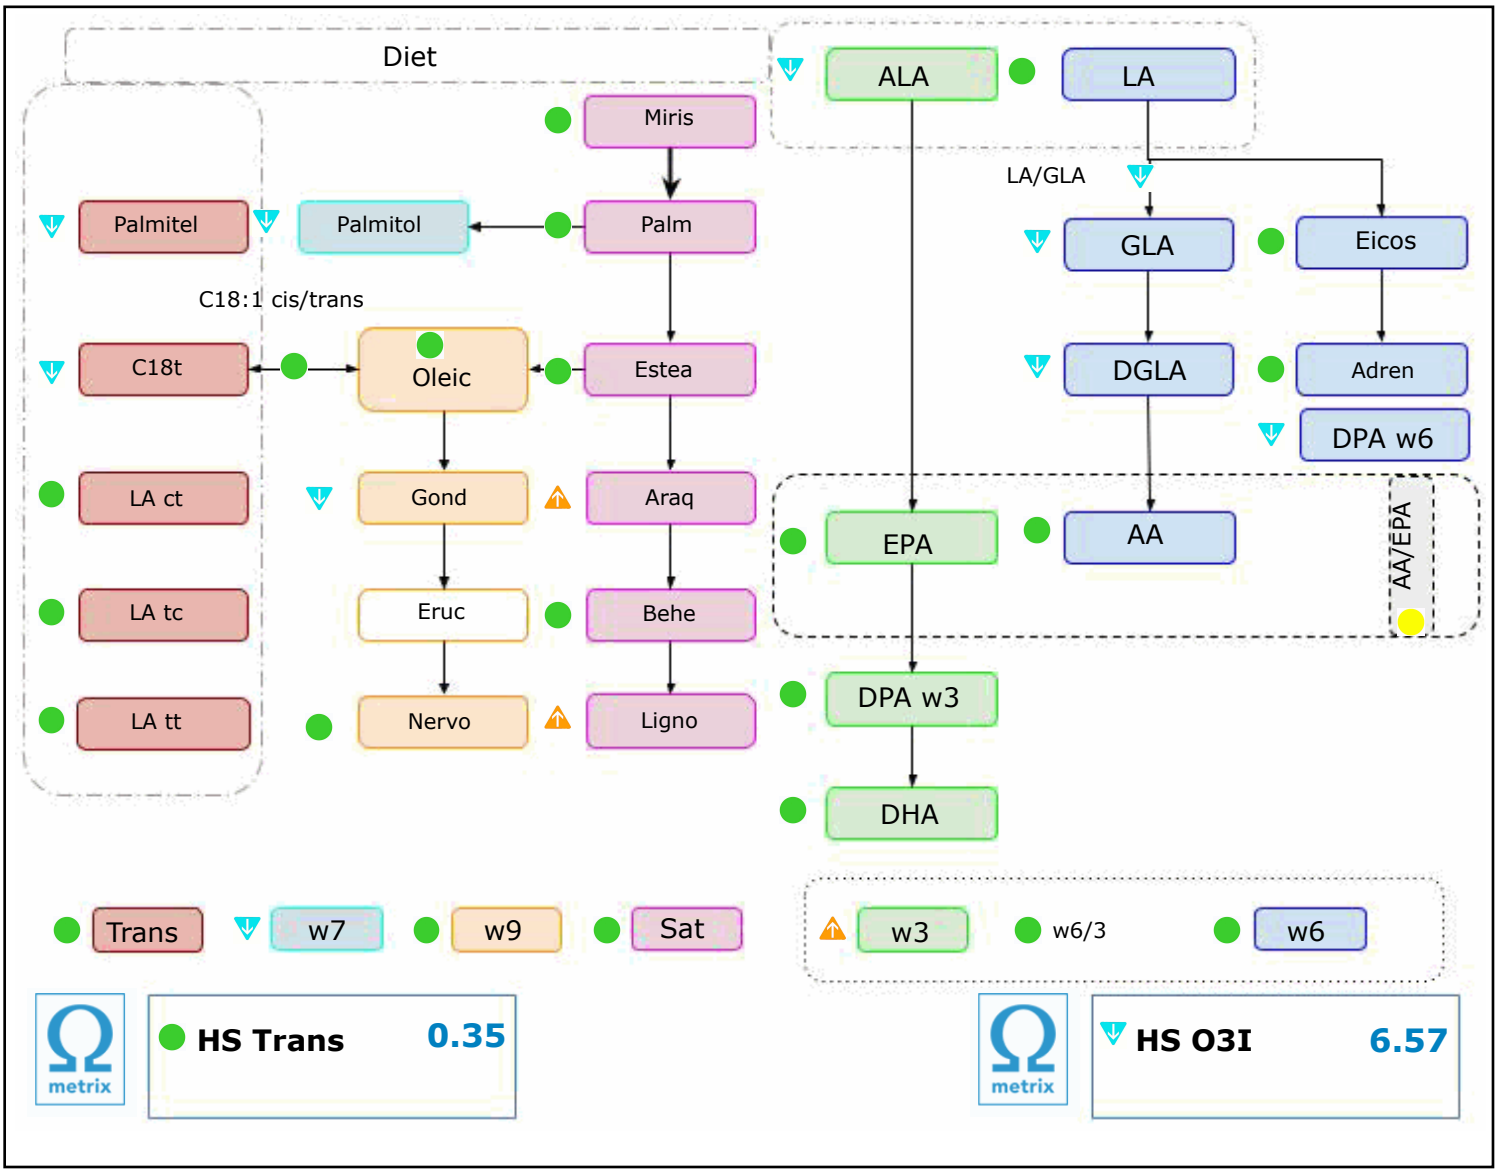

It is recommended to perform this test to control and readjust nutritional imbalances as prevention of the development of inflammatory diseases and their consequences (atherosclerosis, diabetes, depression, cancer ...). It is essential as a tool to assess any nutritional treatment (type of food and supplementation) designed by the professional.

The Laboratory has updated the test method by quantifying fatty acids to improve sensitivity and reduce interference from major compounds.

The reference values shown in this analysis belong to the type of Mediterranean diet.
